Abstract

Records of leucism in tayras (*Eira barbara*) occur sporadically. There were found 18 records in Brazil and we present the most recent record for the southeast region, the last one occurred more than six years ago (2015). We demonstrate that records of leucistic tayras are punctual for the north of the Amazon and the south-central of the Atlantic Forest; and found that the number of records has increased in the last 10 years. Given this scenario, we suggest further research on the species to better understand the conservation status of the species and reasons for the increase in the number of occurrences of leucistic tayras.

Keywords: Camera trap. Conservation. Mustelid. Natural history. White coat.

Introduction

The tayra (*Eira barbara*) is part of the Carnivora order and Mustelidae family. *Eira barbara* is one of the main mammals in inventories of medium and large animals, being widely recorded in Brazil (e.g. MACHADO *et al.*, 2017; MORAIS *et al.*, 2018; OLIVEIRA *et al.*, 2019; SANTIAGO *et al.*, 2020), however in other countries the record is rare (e.g. El Salvador – MARINEROS, 2006). The tayra is a Neotropical species, distributed from sea level to above 2600 m altitude (REYES-PUIG *et al.*, 2015). Individuals have a diurnal pattern, which varies throughout their distribution and seasons. This variation demonstrates broad phenotypic flexibility, which contributes for a wide geographic distribution (VILLAFAÑE-TRUJILLO *et al.*, 2021). This recording is related to its wide distribution and habits predominantly diurnal with their higher frequency of occurrence lower elevations and in areas more distant from human habitation (LIMA; PASSAMANI; ROSA, 2020), which reaches from southern Mexico to Argentina, with records in all Brazilian morphoclimatic domains,

especially in environments with denser vegetation (REIS *et al.*, 2006).

Individuals have a coat with a dark brown tone along the body, becoming darker closer to the head. The head and neck are lighter brown. There are eight phenotypes of the species, not all of them have disruptive coat coloration, besides individual identification is possible due the throat patch (VILLAFAÑE-TRUJILLO *et al.*, 2018) and there are at least three phenotypes in Brazil (PRESLEY, 2000). However, this coat may vary according to geographic region (REIS *et al.*, 2006) or due to rare anomalies (TORTATO; ALTHOFF, 2007; TALAMONI *et al.*, 2017).

Among the rare anomalies of coat color are melanism, increased melanin pigment and consequent darkening of the skin and hair; piebaldism, partial depigmentation (lack of melanocytes) in part of the animal's body; and leucism (MILLER, 2005). Leucism is the occurrence of anomalous whitish coloration of the coat resulting from the total or partial reduction of melanin pigmentation. The albinism is the

exclusive lack of melanin, leucism is the lack of pigmentation in general, which may or may not have a hereditary genetic background. In this case, the entire body may be white or just some parts. To visually differentiate the two conditions, it is necessary to observe the species' eyes. In animals with leucism, the eyes have a normal color, while albinos have pink or red eyes (MILLER, 2005).

This phenotypic condition is still not fully explained, as the expression of this characteristic may be attributed to a recessive mutant allele (BENSCH *et al.*, 2000), or to the absence of Tyrosinase production, an enzyme which favors melanin production (SANCHEZ-FERRER *et al.*, 1995). The albinism and leucism are rare in nature (TALAMONI *et al.*, 2017), however there are records in field reports in the last ten years, as well as specimens deposited in museums (see records in TORTATO; ALTHOFF 2007; AXIMOFF; ROSA, 2016; SOBROZA *et al.*, 2016; TALAMONI *et al.*, 2017; SCRICH *et al.*, 2019). With this note our aim is to add one more record of leucistic tayra *Eira barbara* Lineu, 1758 to São Paulo State, Brazil, and present past records in scientific articles, making a critical analysis.

Material and methods

This record was obtained during fauna studies in Botucatu, São Paulo State, Brazil. The city has a population of 145,155 inhabitants, in an area of 1,482.87 km². The region's economy

is based on agriculture, livestock, and forestry with advances in the industrial sector (IBGE, 2024). The vegetation includes two domains, Cerrado and Atlantic Forest, with AW Koppen climate classification (FRANCO *et al.*, 2023). The annual precipitation is 1500 mm and the average annual temperature is 21.34 °C. Bushnell trap cameras were used, positioned approximately 50 cm high, without attractive bait. The traps were placed in linear transects across the landscape.

Results and discussion

The record was obtained on April 7, 2021 (autumn – dry season), at around 9:28 am in Botucatu city, São Paulo state (22° 57' 55" S 48° 17' 32" W) (Figure 1) in 874 m high. There were found 18 records of tayras with white coat due leucism or albinism (including this note) throughout the Brazilian territory (Table 1; Figure 2). The records in the north of the Amazon are in well-preserved forests of the biome, in line with the direction of expansion of areas of urban agglomerations.

The anomalous coloration could ease the detection of individuals, as it makes it impossible to camouflage in the environment (as mentioned by TALAMONI *et al.*, 2017). Therefore, it is suggested to increase the preservation and management of these areas to maintain population. The records in the south-central

Atlantic Forest deserve special attention, as some of them are from areas that were fully urbanized, such as those made more than a century ago in the center of São Paulo (Parque da Luz – TALAMONI et al., 2017), as well as of the others also ancient which are from specimens in scientific collections. The records from the decade of 2000 are from forest remnants that need special attention to maintain these environments, as they are highly fragmented (RIBEIRO et al., 2009)

and the current environmental policy situation does not favor the maintenance of conservation and preservation aspects (ARAÚJO, 2020).

From a regional point of view, this record is relevant by increasing the regional species pool, and adding the information of pelage color that may be the result of abnormalities of genetic and/or environmental causes. Also, the record could be the result of a recessive gene, or a reduction of a protein, or the high values of

Figure 2. Map with the leucism records in Brazil from previous articles and from this study. The records in articles are in black and our record is in red. The numbers on the map are the same of the Table 1.

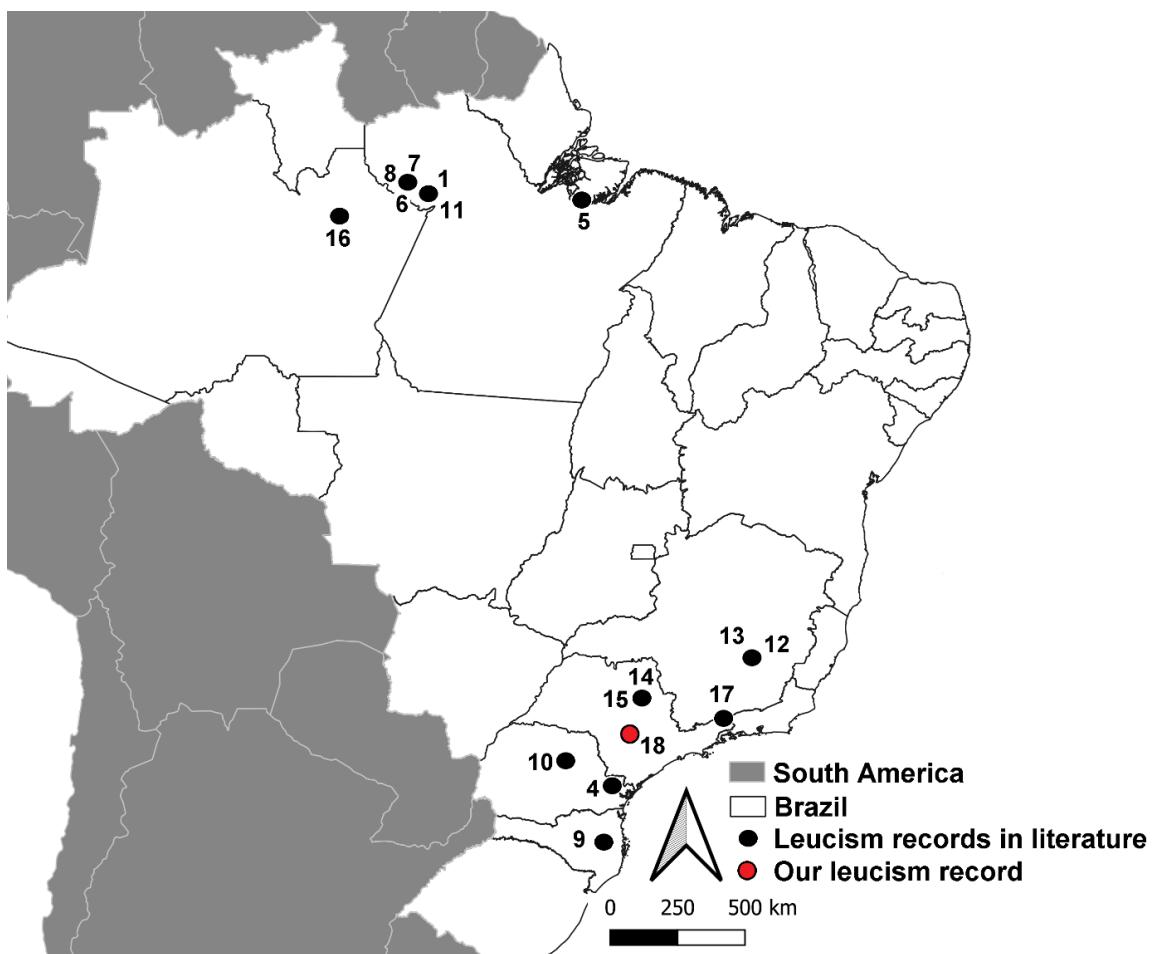

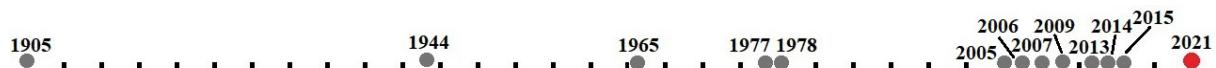

Figure 3. Timeline with documented records of albinism or leucistic tayras in the Brazilian territory. Records in articles are in gray, and the record of this note is in red. Each segment of the timeline represents ~3.6 years.

consanguinity index. More research is suggested for the topic. Furthermore, this record increasing the conservation and preservation status. The amount of tayra's leucism records has been increased in recent years (Figure 3), which raises relevant questions for the conservation of the species.
